

Depth-First Search

Subgraphs

- ◆ A subgraph S of a graph G is a graph such that
 - The vertices of S are a subset of the vertices of G
 - The edges of S are a subset of the edges of G
- ◆ A spanning subgraph of G is a subgraph that contains all the vertices of G

Subgraph

Spanning subgraph

Connectivity

- ◆ A graph is connected if there is a path between every pair of vertices
- ◆ A connected component of a graph G is a maximal connected subgraph of G

Connected graph

Non connected graph with two connected components

Trees and Forests

- ◆ A (free) tree is an undirected graph T such that
 - T is connected
 - T has no cycles

This definition of tree is different from the one of a rooted tree
- ◆ A forest is an undirected graph without cycles
- ◆ The connected components of a forest are trees

Tree

Forest

Spanning Trees and Forests

- ◆ A spanning tree of a connected graph is a spanning subgraph that is a tree
- ◆ A spanning tree is not unique unless the graph is a tree
- ◆ Spanning trees have applications to the design of communication networks
- ◆ A spanning forest of a graph is a spanning subgraph that is a forest

Graph

Spanning tree

Depth-First Search (§ 12.3.1)

- ◆ Depth-first search (DFS) is a general technique for traversing a graph
- ◆ A DFS traversal of a graph G
 - Visits all the vertices and edges of G
 - Determines whether G is connected
 - Computes the connected components of G
 - Computes a spanning forest of G
- ◆ DFS on a graph with n vertices and m edges takes $O(n + m)$ time
- ◆ DFS can be further extended to solve other graph problems
 - Find and report a path between two given vertices
 - Find a cycle in the graph
- ◆ Depth-first search is to graphs what Euler tour is to binary trees

DFS Algorithm

- ◆ The algorithm uses a mechanism for setting and getting "labels" of vertices and edges

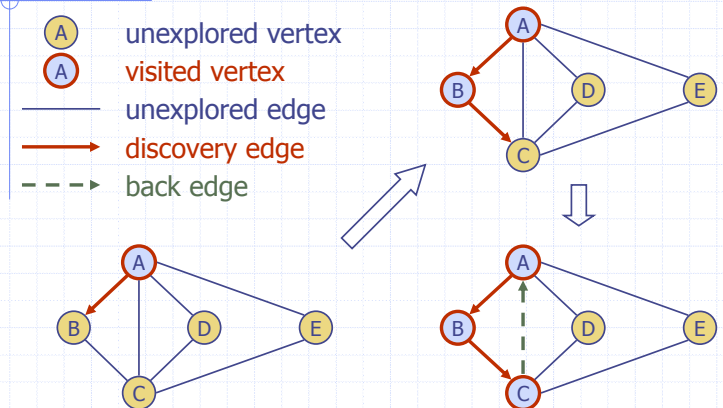

```

Algorithm DFS(G)
  Input graph  $G$ 
  Output labeling of the edges of  $G$ 
  as discovery edges and back edges
  for all  $u \in G.vertices()$ 
    setLabel(u, UNEXPLORED)
  for all  $e \in G.edges()$ 
    setLabel(e, UNEXPLORED)
  for all  $v \in G.vertices()$ 
    if getLabel(v) = UNEXPLORED
      DFS(G, v)
    
```

```

Algorithm DFS(G, v)
  Input graph  $G$  and a start vertex  $v$  of  $G$ 
  Output labeling of the edges of  $G$ 
  in the connected component of  $v$ 
  as discovery edges and back edges
  setLabel(v, VISITED)
  for all  $e \in G.incidentEdges(v)$ 
    if getLabel(e) = UNEXPLORED
       $w \leftarrow opposite(v, e)$ 
      if getLabel(w) = UNEXPLORED
        setLabel(e, DISCOVERY)
        DFS(G, w)
      else
        setLabel(e, BACK)
    
```

Example

Example (cont.)

DFS and Maze Traversal

◆ The DFS algorithm is similar to a classic strategy for exploring a maze

- We mark each intersection, corner and dead end (vertex) visited
- We mark each corridor (edge) traversed
- We keep track of the path back to the entrance (start vertex) by means of a rope (recursion stack)

Properties of DFS

Property 1

$DFS(G, v)$ visits all the vertices and edges in the connected component of v

Property 2

The discovery edges labeled by $DFS(G, v)$ form a spanning tree of the connected component of v

Analysis of DFS

- ◆ Setting/getting a vertex/edge label takes $O(1)$ time
- ◆ Each vertex is labeled twice
 - once as UNEXPLORED
 - once as VISITED
- ◆ Each edge is labeled twice
 - once as UNEXPLORED
 - once as DISCOVERY or BACK
- ◆ Method incidentEdges is called once for each vertex
- ◆ DFS runs in $O(n + m)$ time provided the graph is represented by the adjacency list structure
 - Recall that $\sum_v \deg(v) = 2m$

Path Finding

- ◆ We can specialize the DFS algorithm to find a path between two given vertices u and z using the template method pattern
- ◆ We call $DFS(G, u)$ with u as the start vertex
- ◆ We use a stack S to keep track of the path between the start vertex and the current vertex
- ◆ As soon as destination vertex z is encountered, we return the path as the contents of the stack

```
Algorithm pathDFS( $G, v, z$ )
  setLabel( $v, VISITED$ )
   $S.push(v)$ 
  if  $v = z$ 
    return  $S.elements()$ 
  for all  $e \in G.incidentEdges(v)$ 
    if getLabel( $e$ ) = UNEXPLORED
       $w \leftarrow opposite(v, e)$ 
      if getLabel( $w$ ) = UNEXPLORED
        setLabel( $e, DISCOVERY$ )
         $S.push(e)$ 
        pathDFS( $G, w, z$ )
         $S.pop(e)$ 
      else
        setLabel( $e, BACK$ )
   $S.pop(v)$ 
```

Cycle Finding

- ◆ We can specialize the DFS algorithm to find a simple cycle using the template method pattern
- ◆ We use a stack S to keep track of the path between the start vertex and the current vertex
- ◆ As soon as a back edge (v, w) is encountered, we return the cycle as the portion of the stack from the top to vertex w

```
Algorithm cycleDFS( $G, v, z$ )
  setLabel( $v, VISITED$ )
   $S.push(v)$ 
  for all  $e \in G.incidentEdges(v)$ 
    if getLabel( $e$ ) = UNEXPLORED
       $w \leftarrow opposite(v, e)$ 
       $S.push(e)$ 
      if getLabel( $w$ ) = UNEXPLORED
        setLabel( $e, DISCOVERY$ )
        pathDFS( $G, w, z$ )
         $S.pop(e)$ 
      else
         $T \leftarrow$  new empty stack
        repeat
           $o \leftarrow S.pop()$ 
           $T.push(o)$ 
        until  $o = w$ 
        return  $T.elements()$ 
   $S.pop(v)$ 
```
