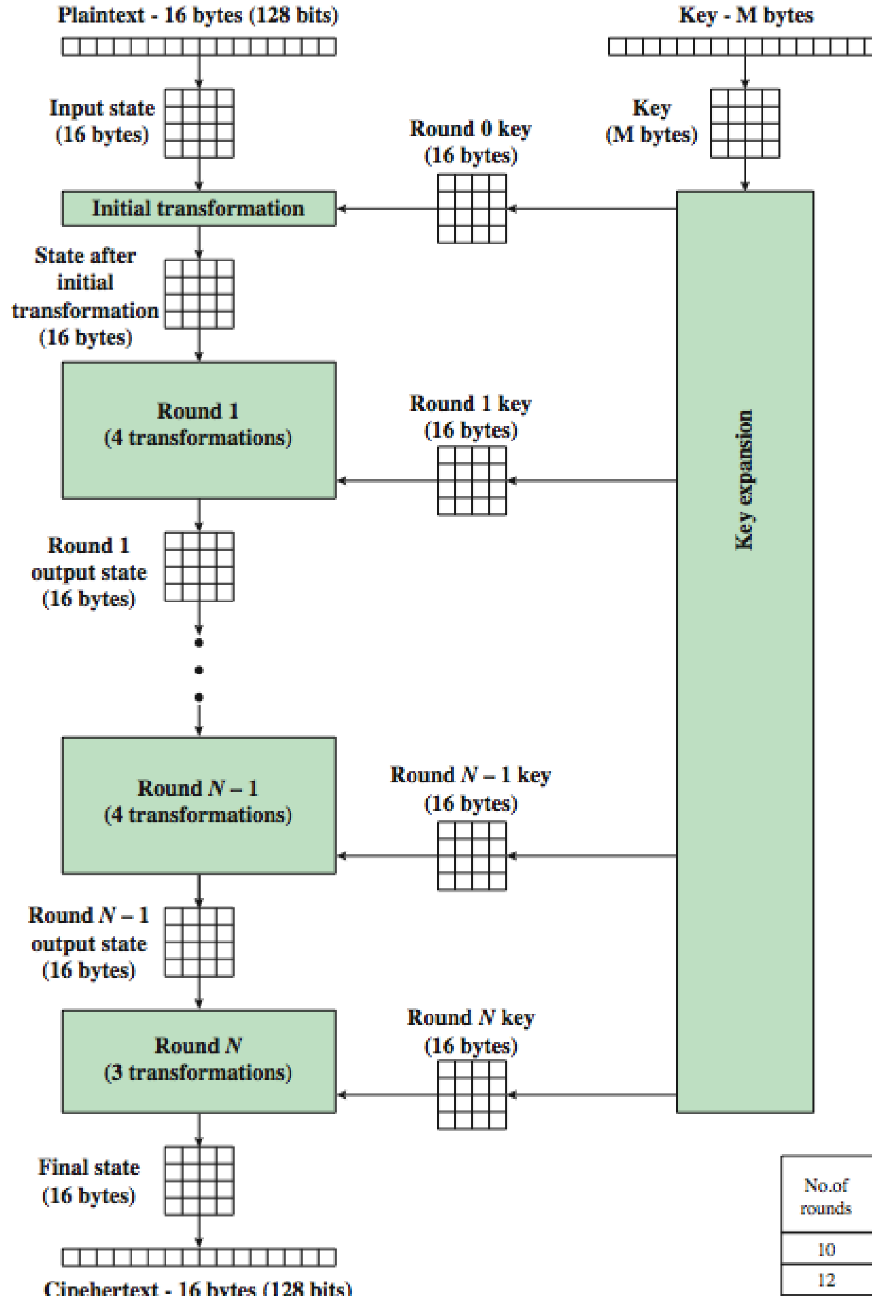
Chapter 5

Advanced Encryption Standard (AES) Cipher

The AES Cipher

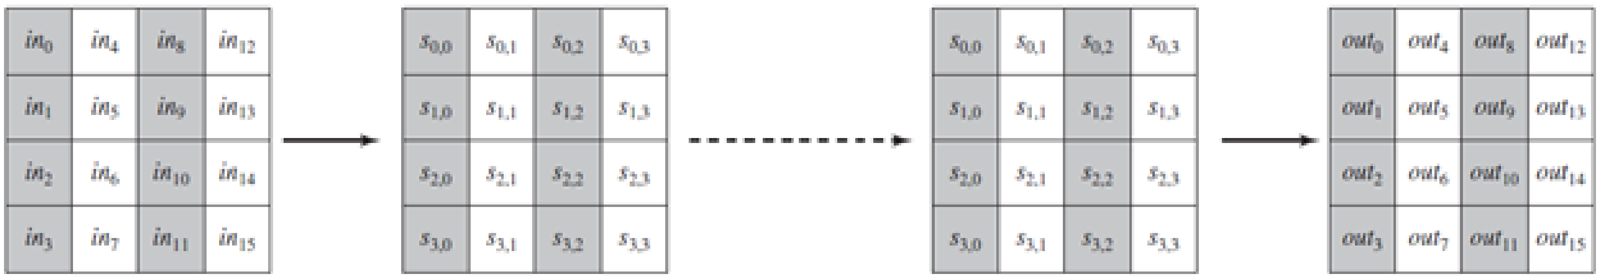
- designed by Rijmen-Daemen in Belgium
- AES general structure :
  - Block Size : 128 bit (plaintext)
  - Key sizes : 128/192/256 bits (AES-128, AES-192, AES-256)
- An iterative rather than Feistel Cipher
  - operates on entire data block in every round rather than feistel operate on halves at a time.
  - processes data as block of 4 columns of 4 bytes (4x4 Matrix)
- designed to be:
  - resistant against known attacks
  - speed and code compactness on many CPUs
  - Byte Operations: Easy to implement in software.

AES Encryption Process



No.of rounds	Key Length (bytes)
10	16
12	24
14	32

The input to the encryption and decryption algorithms is a single 128-bit block as a square matrix of bytes. This block is copied into the **State** array, which is modified at each stage of encryption or decryption. After the final stage, **State** is copied to an output matrix.



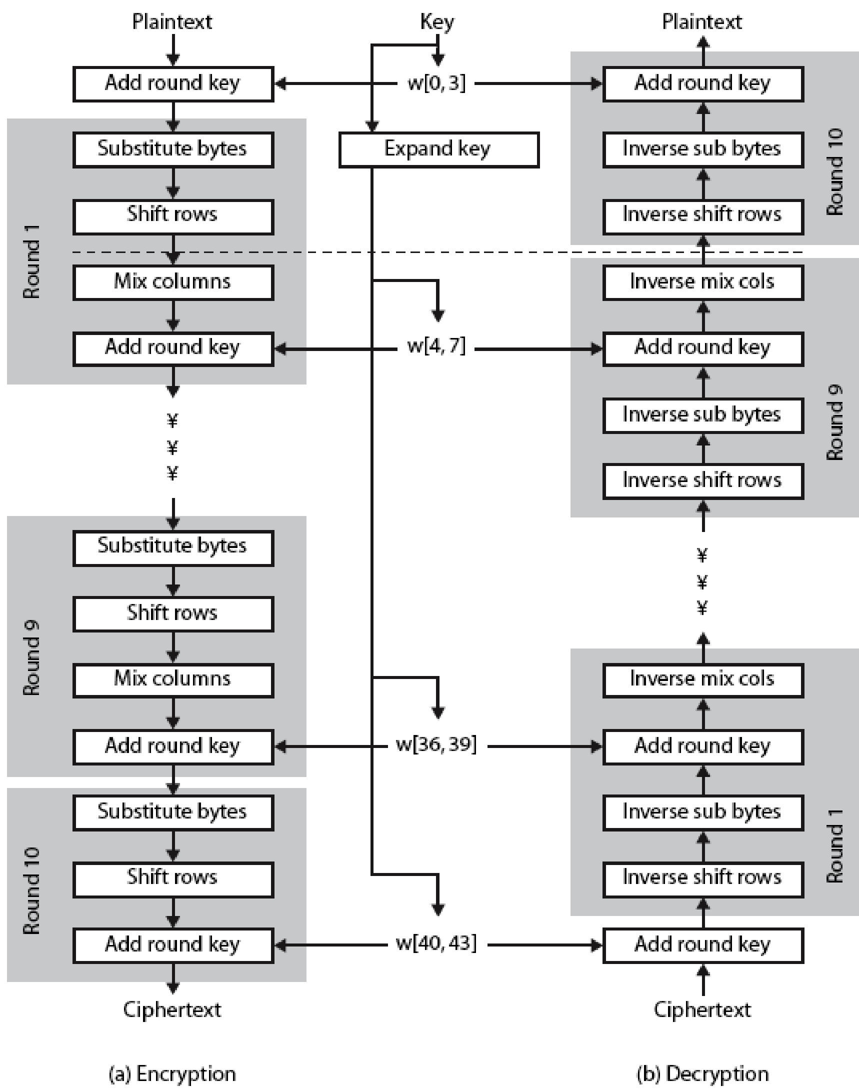
Input, state array, and output

The key as a square matrix of bytes expanded into an array of key schedule words. Each word is four bytes, and the total key schedule is 44 words for the 128-bit key.

Key and expanded key

Key Size (words/bytes/bits)	4/16/128	6/24/192	8/32/256
Plaintext Block Size (words/bytes/bits)	4/16/128	4/16/128	4/16/128
Number of Rounds	10	12	14
Round Key Size (words/bytes/bits)	4/16/128	4/16/128	4/16/128
Expanded Key Size (words/bytes)	44/176	52/208	60/240

AES Structure



The cipher consists of N rounds, where the number of rounds depends on the key length:

10 rounds for a 16-byte key;

12 rounds for a 24-byte key; and

14 rounds for a 32-byte key.

The first N – 1 rounds consist of four distinct transformation functions:

SubBytes, ShiftRows, MixColumns, and AddRoundKey

The final round contains only 3 transformation, and there is a initial single transformation (AddRoundKey) before the first round, which can be considered Round 0.

Each transformation takes one or more 4 x 4 matrices as input and produces a 4 x 4 matrix as output.

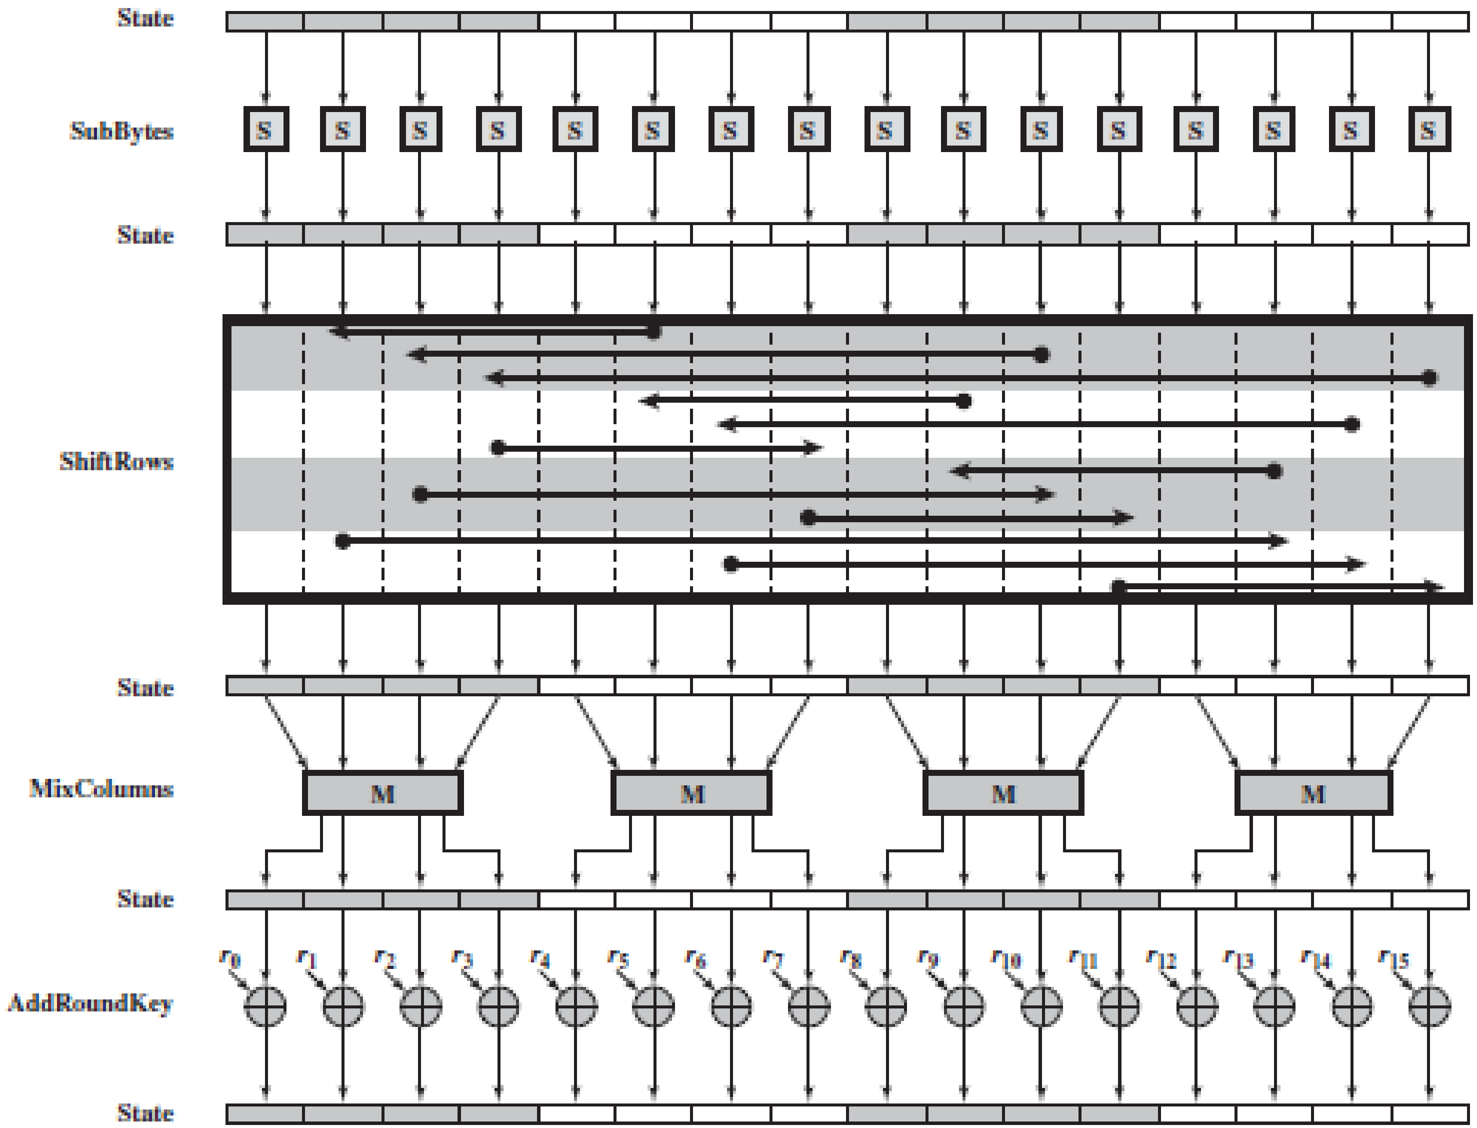
The output of each round is a 4 x 4 matrix, with the output of the final round being the ciphertext.

Also, the key expansion function generates N + 1 round keys, each of which is a distinct 4 x 4 matrix. Each round key serve as one of the inputs to the AddRoundKey transformation in each round.

AES Transformation Functions

- Substitute Bytes
- Shift Rows
- Mix Columns
- Add Round Key

AES Encryption Round



Substitute Bytes Transformation

- Substitute each byte of state and replace it by byte indexed by row (left 4-bits) & column (right 4-bits).
- Use an S-box to perform a byte-by-byte substitution of the block

The Byte Substitution operates on each byte of state independently, with the input byte used to index a row/col in the table to retrieve the substituted value.

Shift Rows Transformation

- a circular byte shift in each each
  - 1st row is unchanged
  - 2nd row does 1 byte circular shift to left
  - 3rd row does 2 byte circular shift to left
  - 4th row does 3 byte circular shift to left

- decrypt inverts using shifts to right (opposite direction).

- Spread 4 bytes of one column to all columns

Mix Columns Transformation

- each column is processed separately
- each byte is replaced by a value dependent on all 4 bytes in the column
- effectively a matrix multiplication in $GF(2^8)$ using prime poly $m(x) = x^8+x^4+x^3+x+1$

$$\begin{bmatrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{bmatrix} \begin{bmatrix} s_{0,0} & s_{0,1} & s_{0,2} & s_{0,3} \\ s_{1,0} & s_{1,1} & s_{1,2} & s_{1,3} \\ s_{2,0} & s_{2,1} & s_{2,2} & s_{2,3} \\ s_{3,0} & s_{3,1} & s_{3,2} & s_{3,3} \end{bmatrix} = \begin{bmatrix} s'_{0,0} & s'_{0,1} & s'_{0,2} & s'_{0,3} \\ s'_{1,0} & s'_{1,1} & s'_{1,2} & s'_{1,3} \\ s'_{2,0} & s'_{2,1} & s'_{2,2} & s'_{2,3} \\ s'_{3,0} & s'_{3,1} & s'_{3,2} & s'_{3,3} \end{bmatrix}$$

Add Round Key Transformation

- XOR state with 128-bits of the round key
- inverse for decryption identical
  - since XOR own inverse, with reversed keys
- designed to be as simple as possible and requires other stages for complexity / security

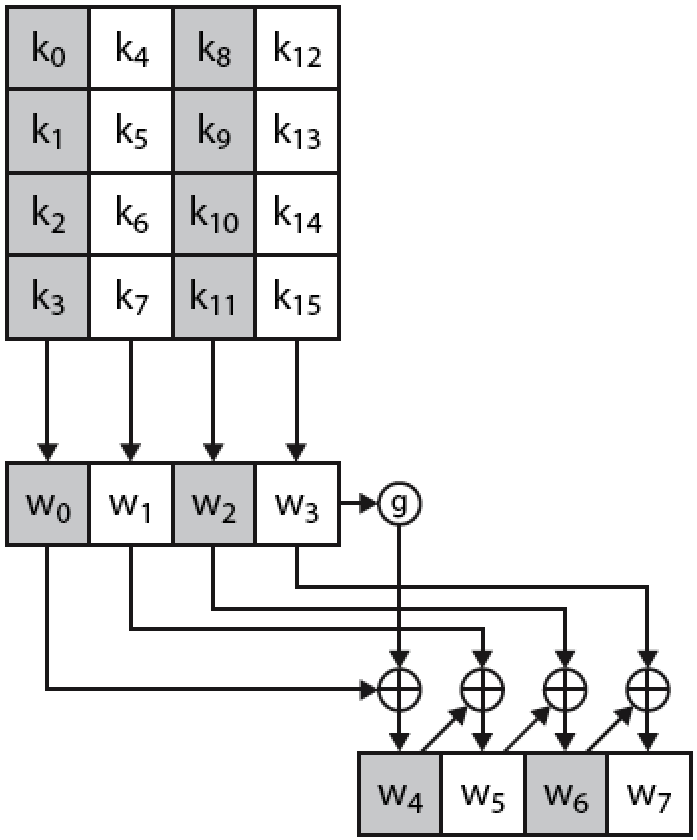
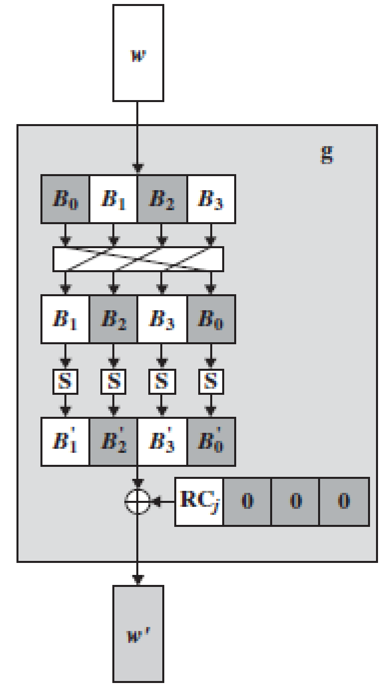
AES Key Expansion

- takes 4 word 128-bit (16-byte) key and expands into array of 44/52/60 32-bit words
- start by copying key into first 4 words
- then loop creating words that depend on values in previous & 4 places back
  - in 3 of 4 cases just XOR these together
  - 1st word in 4 has rotate + S-box + XOR round constant on previous, before XOR 4th back

AES Key Expansion





j	1	2	3	4	5	6	7	8	9	10
RC[j]	01	02	04	08	10	20	40	80	1B	36

The first block of the AES Key Expansion is shown. It shows each group of 4 bytes in the key being assigned to the first 4 words, then the calculation of the next 4 words based on the values of the previous 4 words, which is repeated enough times to create all the necessary subkey information.

Key Expansion Rationale

- designed to resist known attacks
- design criteria included
  - knowing part key insufficient to find many more
  - invertible transformation
  - fast on wide range of CPU's
  - use round constants to break symmetry
  - diffuse key bits into round keys
  - enough non-linearity to hinder analysis
  - simplicity of description

Table shows the expansion of the 16-byte key into 10 round keys.

As previously explained, this process is performed word by word, with each four-byte word occupying one column of the word round key matrix.

The left hand column shows the four round key words generated for each round.

The right hand column shows the steps used to generate the auxiliary word used in key expansion.

We begin, with the key itself serving as the round key for round 0.

Next, the progression of the state matrix through the AES encryption process.
The first column shows the value of the state matrix at the start of a round.
For the first row, the state matrix is just the matrix arrangement of the plaintext.
The second, third, and fourth columns show the value of the state matrix for that round after the SubBytes, ShiftRows, and MixColumns transformations, respectively.
The fifth column shows the round key
The first column shows the value of the state matrix resulting from the bitwise XOR of the state after the preceding MixColumns with the round key for the preceding round.

AES Decryption

- AES decryption is not identical to encryption since steps done in reverse (The sequence of transformations for decryption differs from that for encryption although the form of the key schedules is the same).
- but can define an equivalent inverse cipher with steps as for encryption
  - but using inverses of each step
  - with a different key schedule
- works since result is unchanged when
  - swap byte substitution & shift rows
  - swap mix columns & add (tweaked) round key
