Spring – 2023 (3<sup>rd</sup> Sem. 1444H) <u>Chapter 4</u>:

Structured Analysis and Functional Architecture Design – p2 – DFD – i - Fundamentals

Prepared by: Ahmed M. El-Sherbeeny, PhD

• 1

## **Lesson Overview**

- Modeling IIS (p1)
- Integrated Computer-Aided Manufacturing Definition 0 (IDEF0) – (p1)
- Data Flow Diagram (DFD) (p2)
  - i. Fundamentals
  - ii. Diagramming Rules
  - iii. Case Studies

## **DFD – part i – Fundamentals**

- Introduction to DFD
- DFA/DFD Modeling Primitives

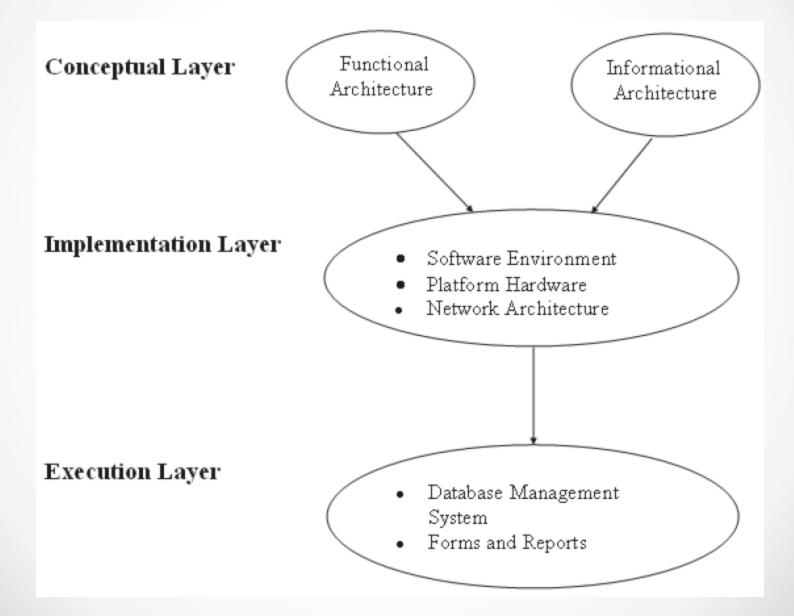

# **Functional/Process Modeling:**

# 2. Data Flow Diagram (DFD)

# **Introduction to DFD**

# **Layers of IS Design Process**

# **Functional/Process Modeling**

- Remember: two methodologies for designing a functional architecture, known as "structured analysis" techniques:
  - data flow diagrams (1979), widely used by information system professionals in all industries
  - structured analysis and design technique (SADT) (1988), adapted for manufacturing enterprises under the name integrated computer-aided manufacturing definition 0 (IDEF0)
  - Both methodologies are based on graphical notations used to describe information flows among processes of the enterprise being documented

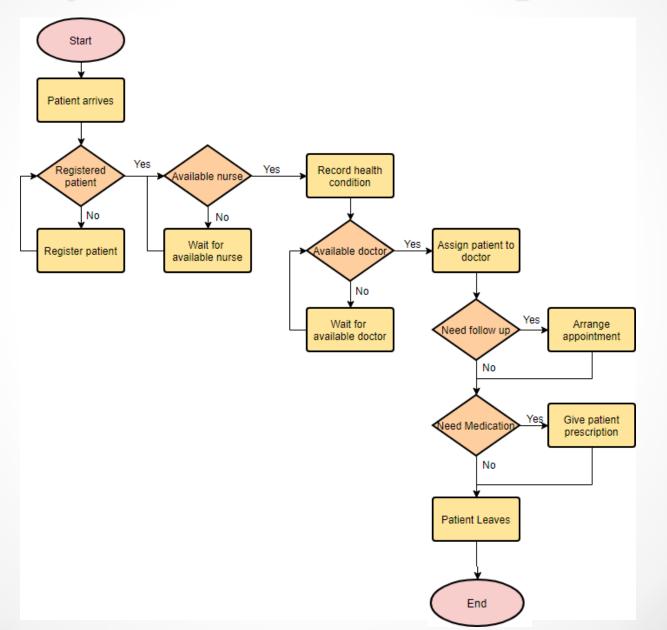

# **Functional/Process Modeling**

 Graphically represent the processes that capture, manipulate, store, and distribute data:
 between a system and its environment

and among system components

- Useful for depicting purely logical information flows
- DFDs differ from system flowcharts which depict a procedure (<u>see next slide</u>)

## System Flowchart (example)

## **DFDs vs. IDEF0**

- Data Flow Diagrams (DFD), aka Data Flow Analysis (DFA) is an alternative to IDEF0 that is widely used in all industries, both in modeling:
  - o manufacturing, and

service processes and operations

- It differs from IDEF0 in that it focuses exclusively on business processes and the information that flows among processes, ignoring (unlike IDEF0):
   material flows
  - o mechanisms, and

#### o controls

# **DFA/DFD Modeling Primitives**

• 11

# **Components of DFD**

- Data flow diagrams are constructed using four symbols:
  - Process
  - Data Flow
  - Data Store
  - $\circ$  Sources and Sinks

#### • Process:

- work or actions performed on data (inside the system) so that they are transformed, stored, or distributed
- represents people/procedures that transform data
- each process must have data entering it and exiting it (otherwise, it does not belong in a DFD)
- o <u>Gane and Sarson symbol</u>:
  - upper portion is used to indicate the number of the process
  - lower portion is a name for the process (e.g. Generate Paycheck, Calculate Overtime Pay)

#### • Data flow:

- arrows indicate the direction in which the data move (i.e. "data in motion," from one place in a system to another)
- "data" is a general concept; e.g. data sent to a computer file, or information given from one process to another process
- remember, arrows are not used to indicate physical flow of materials (as in IDEF0)
- arrow is labeled with a meaningful name for data in motion (e.g. Customer Order, Sales Receipt, or Paycheck)

#### Data store:

- place where data are preserved as a record inside the system ("data at rest")
- e.g. computer file or paper filing cabinet
- note, there is no explicit construct in IDEF0 that is analogous to a data store
- o <u>Gane and Sarson symbol</u>:
  - left end: a small box used to number the data store
  - inside the main part of the rectangle is a meaningful label for the data store (e.g. Student File, Transcripts, or Roster of Classes)

15

#### Sources and sinks:

- external entity that is origin –source– or destination –sink– of data (outside the system)
- it represents how at the boundaries, DFA system interacts with outside people, processes, organizations, other information systems (note, this is similar to IDEF0 model)
- Sources: entities outside the system that provide data input to the system (usually trigger events in the system); e.g. customer
- Sinks: entities outside the system that receive data
- note, same entity may be both a source and a sink if it both sends data to and receives data from the system
- <u>sources/sinks</u> have a name that states what the external agent is (e.g. Customer, Teller, Inventory Control System)

#### Sources and sinks (cont.):

- Sources and sinks, do not consider the following:
  Interactions that occur between sources and sinks
  - What a source or sink does with information (i.e. source or sink is a "black box")
  - How to control or redesign a source or sink (assumed to be fixed)
  - How to provide sources and sinks direct access to stored data (since they cannot directly access or manipulate data stored within the system)

# **DFD Symbols/Notation**

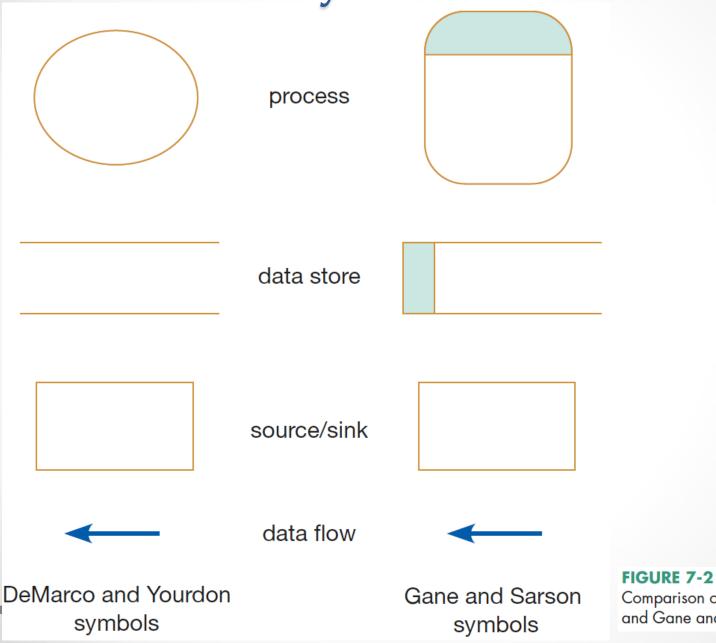

FIGURE 7-2 Comparison of DeMarco and Yourdon and Gane and Sarson DFD symbol sets

## **DFD Symbols/Notation (contd.)**

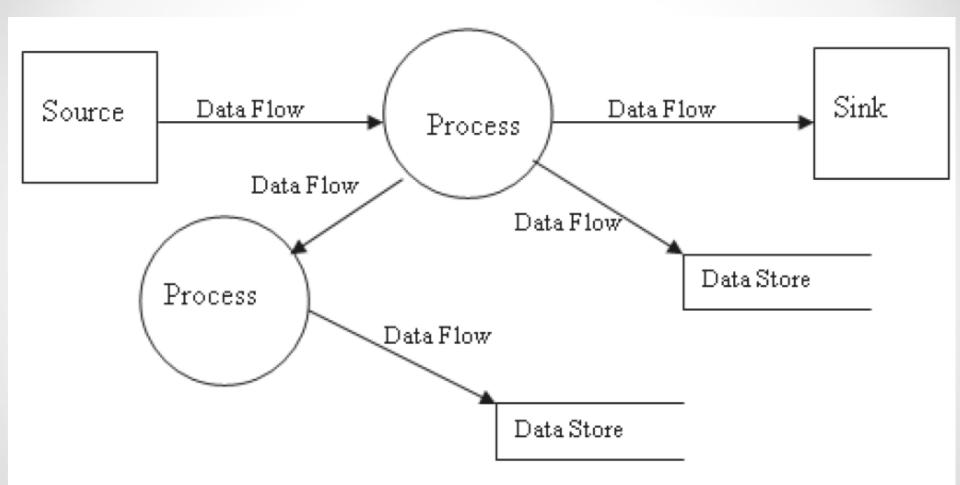

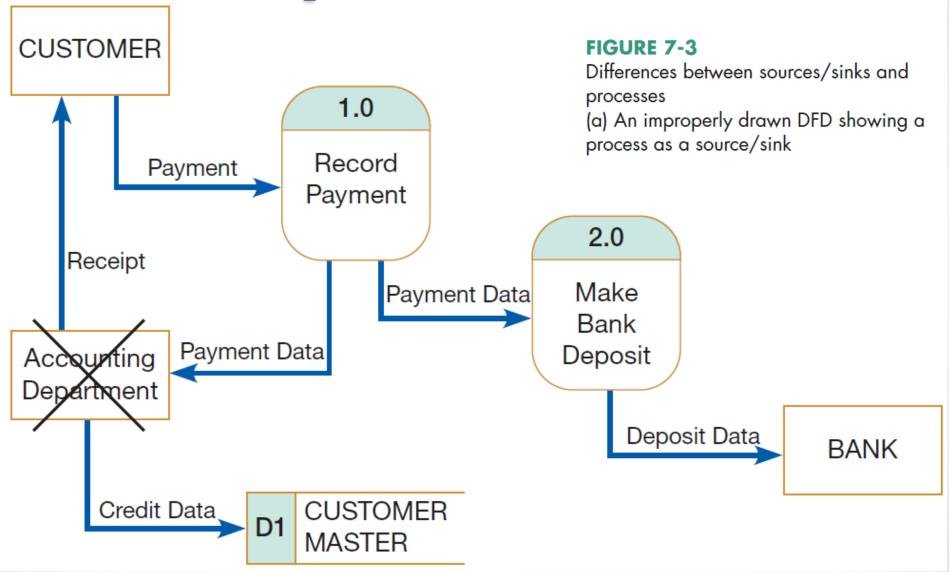

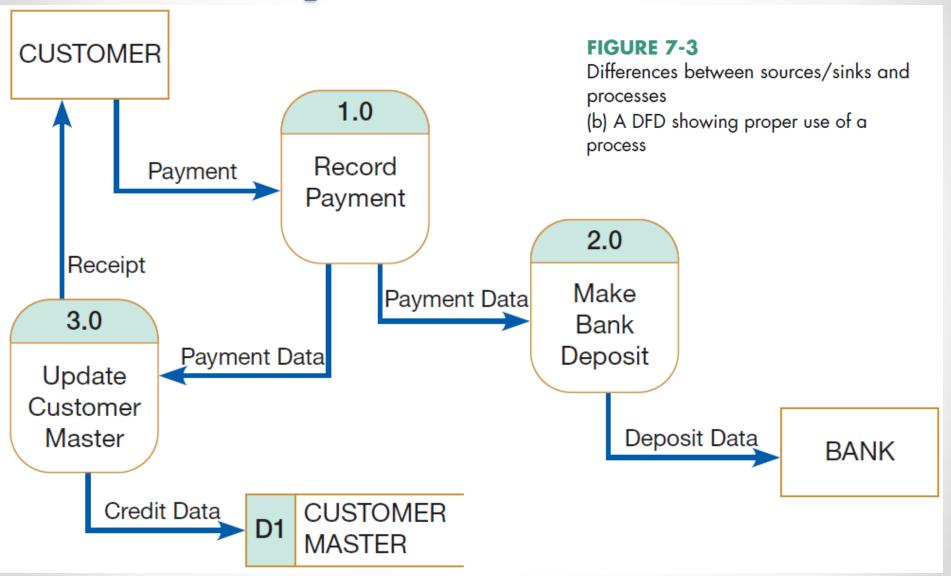

Figure 4.14 Generic data flow diagram.

#### Sources and sinks (cont.):

- Careful not to confuse whether something is a source/sink or a process within a system:
  - occurs most often when the data flows in a system cross office or departmental boundaries (see <u>e.g.</u>)
  - students are then tempted to identify the second office as a source/sink (to emphasize that data moved from one physical location to another)
  - we are not concerned with where the data are physically located, rather how they are moving through the system and how they are being processed
  - if the other office is controlled by your system  $\Rightarrow$  then you should represent the second office as one or more <u>processes</u>
