Manufacturing Engineering Technology in SI Units, 6<sup>th</sup> Edition

Chapter 25:

Machining Centers, Machine Tool Structures and Machining

Economics

# Chapter Outline

- □ <u>Introduction</u>
- Machining Centers
- Machine-tool Structures
- <u>Vibration and Chatter in Machining Operations</u>
- High-speed Machining
- Hard Machining
- Ultraprecision Machining
- Machining Economics

- Limitations of machining/material removal operations:
- Wasted material (although may be small)
- Longer time (vs. forming/shaping): cutting/non-cutting
- 3. Require more energy (vs. forming/shaping)
- 4. Adverse effects on surface quality / properties of product
- Importance of machining (despite above):
- Producing complex workpiece shapes (e.g. internal features)
- 2. High dimensional accuracy / surface finish

- Costs/factors involved with machining:
- Machine tools, work-holding devices, fixtures and cutting tools
- Labor and overhead
- Setting up time (machine for operation)
- 4. Material handling and movement (e.g. loading blank, unloading machine part)
- 5. Gaging for dimensional accuracy and surface finish
- 6. Cutting times and non-cutting time

#### Minimizing Machining Cost per Piece

- Important in all manufacturing processes to minimize:
  - Machining cost per piece,  $C_p$
  - Machining *time* per piece,  $T_p$
- Various approaches exist (using software)
- Important: input data must be accurate and up to date to be reliable
- We show here simple/popular method of analyzing machining cost in turning operation

#### Cont. Minimizing Machining Cost per Piece

Total machining cost per piece,  $C_p$ , in turning is

$$C_p = C_m + C_s + C_l + C_t$$

 $C_m = Machining cost$ 

 $C_s$  = Cost of setting up for machining—including mounting the cutter, setting up fixtures, and preparing the machine tool for the operation

 $C_I$  = Cost of loading, unloading, and machine handling

C<sub>t</sub> = Tooling cost, often only about 5% of the total cutting operation. Consequently, using the least expensive tool is not always an effective way of reducing machining costs

 Following slides: discuss each of these costs in more detail

#### Cont. Minimizing Machining Cost per Piece

$$C_p = C_m + C_s + C_l + C_t$$

**Machining cost** per piece,  $C_m$ , is given by:

$$C_m = T_m \big( L_m + B_m \big)$$

- $\blacksquare$   $T_m$ : machining time per piece
- $lue{L}_m$ : labor cost of production personnel per hour
- $\blacksquare$   $B_m$ : burden rate (aka overhead charge), including:
  - Depreciation
  - Maintenance
  - Indirect labor, etc.
- The **setup cost**,  $C_s$ , is fixed amount (in \$) per piece

#### Cont. Minimizing Machining Cost per Piece

$$C_p = C_m + C_s + C_l + C_t$$

**Loading**/unloading, machine-handling **cost**,  $C_l$ , per piece:

$$C_l = T_l \big( L_m + B_m \big)$$

- $\blacksquare$   $T_l$ : time required to,
  - load/unload part
  - change speeds
  - change feed rates, etc.
- $\Box$   $L_m$  and  $B_m$ : see last slide

#### Cont. Minimizing Machining Cost per Piece

$$C_p = C_m + C_s + C_l + C_t$$

 $\Box$  The **tooling cost**,  $C_t$ , per piece:

$$C_t = \frac{1}{N_i} \left[ T_c (L_m + B_m) + D_i \right] + \frac{1}{N_f} \left[ T_i (L_m + B_m) \right]$$

- $lue{N}_i$ : numbered of parts machined per insert
- $\square$   $N_f$ : numbered of parts that can produced per insert face
- $T_c$ : time required to change the insert
- $T_i$ : time required to index the insert
- $D_i$ : depreciation of insert (in \$)

#### Cont. Minimizing Machining Cost per Piece

The time required to produce one part is

$$T_p = T_l + T_m + \frac{T_c}{N_i} + \frac{T_i}{N_f}$$

- $T_m$ : calculated for each particular operation
- Example: for turning:

Example: for turning:
$$T_m = \frac{L}{fN} = \frac{\pi LD}{fV}$$

• L: length of cut

- f: feed
- N: angular speed (rpm) of the workpiece
- D: workpiece diameter
- V: cutting speed (note, appropriate units must be used)

#### **Cont. Minimizing Machining Cost per Piece**

- From the Taylor tool-life equation,
- $T = \left(\frac{C}{V}\right)^{1/N}$
- *T*: time (*min*) to reach a certain flank wear (before regrinding/changing insert)
- The number of pieces per insert face:
- Number of pieces per insert:

 $N_i = mN_f = \frac{mT}{T_m}$ 

- m: number of faces actually used
  - Note, *m*: not necessarily number of faces per insert
  - Reason: not all faces are used before insert is discarded
- $\square$  Combining T and  $T_m$  in  $N_i$ :

$$N_i = \frac{mfC^{1/m}}{\pi LDV^{(1/n)-1}}$$

#### Cont. Minimizing Machining Cost per Piece

- $\square$  We now seek to determine optimum  $V(V_o)$  and  $T(T_o)$
- $\square$  First we find  $V_o$  and  $T_o$  for **min. cost**,  $C_p$
- $\square$  We differentiate  $C_p$  with respect to V and set it to zero,

$$\Rightarrow V_0 = \frac{\frac{\partial C_p}{\partial V} = 0}{\left(\frac{1}{n} - 1\right)^n \left\{\frac{1}{m} \left[T_c \left(L_m + B_m\right) + D_i\right] + T_i \left(L_m + B_m\right)\right\}^n}$$

$$T_0 = \left(\frac{1}{n} - 1\right) \frac{1}{m} \left[T_c \left(L_m + B_m\right) + D_i\right] + T_i \left(L_m + B_m\right)}{L_m + R_m}$$

#### Cont. Minimizing Machining Cost per Piece

- $\square$  Again we seek to determine optimum  $V(V_o)$  and  $T(T_o)$
- $\square$  Now we find  $V_o$  and  $T_o$  for max. prodon, i.e. min.  $T_p$
- $\square$  We differentiate  $T_p$  with respect to V and set it to zero,

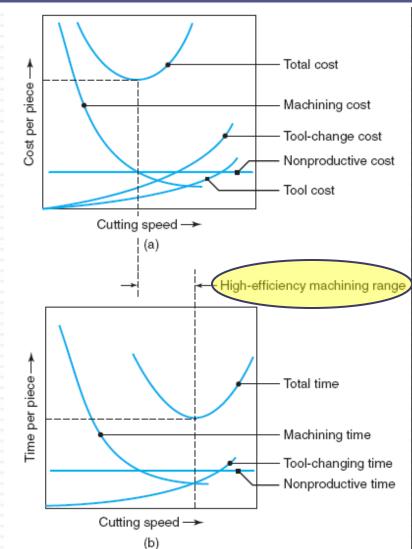

$$\frac{\partial T_p}{\partial V} = 0$$

$$\Rightarrow V_0 = \frac{C}{\left[ \left( \frac{1}{n} - 1 \right) \left( \frac{T_c}{m} + T_i \right) \right]^n}$$

$$T_0 = \left(\frac{1}{n} - 1\right) \left(\frac{T_c}{m} + T_i\right)$$

#### Cont. Minimizing $C_p$ per Piece

- $\square$  Qualitative plot of  $C_p$ /piece
  - Note,  $C_p$  also depends on req. surface finish: better S.F.  $\Rightarrow$  higher  $C_p$
  - Note,  $V_o = V @ C_{p,min}$
- Qualitative plot of  $T_p$ /piece
   (i.e. production rate)
  - Note,  $V_o = V @ T_{p,min}$
  - Range bet. Two  $V_o$ 's is: "high-efficiency machining range"

#### Cont. Minimizing Machining Cost per Piece

- Final notes
  - Important to have accurate data, since small changes in V greatly affect  $C_{p,min}$  and  $T_{p,min}$  (see last slide)
  - Previous analysis can be done for all manufacturing processes:
    - E.g. Cost/part in sand casting uses
    - E.g. Cost/part in powder metallurgy, etc.
