# Chapter 11 Chi-Square Tests 

## Contingency Tables

- Useful in situations comparing multiple population proportions
- Used to classify sample observations according to two or more characteristics
- Also called a cross-classification table.

Textbook : P410 : Section 11.1 Paragraph 1\&2 / Table 11.1

The properties of the chi square distribution.

- Is continuous distribution.
- Positive skewed curve (skewed to the right curve).
- It is not symmetric curve.

## Type of $\chi^{2}$ tests :

1. Chi-Square Test for the difference between two proportions.
2. Chi-Square Test for the difference among more than two proportions.
3. Chi-Square Test of independence.

## Chi-Square Test for the difference between two proportions.

Step (1): State the null and alternate hypotheses :
$\mathrm{H}_{0}$ : The two proportions should be the same
$\mathrm{H}_{1}$ : The two proportions should not be the same
Step (2): Select the level of significance ( $\alpha$ )
Step (3): The test statistic

$$
\chi_{S T A T}^{2}=\sum_{\text {all cells }} \frac{\left(f_{o}-f_{e}\right)^{2}}{f_{e}}
$$

■ where:
$\mathrm{f}_{\mathrm{o}}$ : observed frequency in a particular cell .
$\mathrm{f}_{\mathrm{e}}$ : expected frequency in a particular cell if $\mathrm{H}_{0}$ is true
(Assumed: each cell in the contingency table has expected frequency of at least 5)
"Slide 7"

$$
f_{e}=\frac{\text { rowtotal } \times \text { columntotal }}{n}
$$

or
$\overline{\mathrm{P}} *$ Observed frequency in a particular cell.

$$
\overline{\mathrm{P}} \text { : the overall Porportion }=\frac{X_{1}+X_{2}}{n_{1}+n_{2}}
$$

(Slide 9)
Step (4): The critical value (Textbook : P547: $\chi^{2}$ table)
$\mathrm{df}=(\mathrm{r}-1)(\mathrm{c}-1)=(2-1)(2-1)=1$
$\chi_{(\alpha, 1)}^{2}$
(Slide 7)
Step (5) : The $\chi_{S}^{2}$ tat $\quad$ test statistic approximately follows a chi-squared distribution Reject $\mathrm{H}_{0}$ If $\quad \chi_{\text {Stat }}^{2}>\chi_{(\alpha, 1)}^{2}$ otherwise, do not reject $\mathrm{H}_{0}$

## Example (1): (Slide 8)

Suppose we examine a sample of 300 children Left-Handed vs. Gender. Sample results organized in a contingency table: "Slide 4-9"

| Gender | Hand Preference |  |  |
| :---: | :---: | :---: | :---: |
|  | Left | Right | Total |
| Female | 12 | 108 | 120 |
| Male | 24 | 156 | 180 |
| Total | 36 | 264 | 300 |

Test where the Proportion of females who are left handed is equal to the proportion of males who are left handed ( $\alpha=0.05$ ).

## Solution :

## Step (1):

$\mathrm{H}_{0}: \pi_{1}=\pi_{2}$ (Proportion of females who are left handed is equal to the proportion of males who are left handed)
$\mathrm{H}_{1}: \pi_{1} \neq \pi_{2} \quad$ (The two proportions are not the same)
Step (2): The level of significance ( $\alpha=0.05$ ).

$$
\chi_{(2-1)(2-1), 0.05}^{2}=\chi_{1 \times 1,0.05}^{2}=\chi_{1,0.05=3.841}^{2}
$$

Step (3): The test statistic

| Gender | Hand Preference |  |  |
| :---: | :---: | :---: | :---: |
|  | Left | Right | Total |
| Female |  | 108 105.6 | 120 |
| Male | $\begin{array}{\|rrr} \hline 24 & 21.6 \\ \hline \end{array}$ | $\begin{array}{\|c\|c} \hline 156 & 158.4 \\ \hline \end{array}$ | 180 |
| Total | 36 | 264 | 300 |

$f_{e}=\frac{\text { rowtotal } \times \text { columntotal }}{n}$
$f_{\text {row, column }}=f_{r, c}$
For example: $\mathrm{f}_{11}=\frac{120 \times 36}{300}=14.4, \mathrm{f}_{12}=\frac{120 \times 264}{300}=105.6$,

$$
\mathrm{f}_{21}=\frac{180 \times 36}{300}=21.6, \mathrm{f}_{22}=\frac{180 \times 264}{300}=158.4
$$

Totals for the observaed and expected frequencies are the same
Totals for the observaed frequencies $=12+108+24+156=300$
Totals for the expected frequencies $=14.4+105.6+21.6+158.4=300$

$$
\begin{aligned}
\chi_{\text {STAT }}^{2} & =\sum_{\text {all cells }} \frac{\left(\mathrm{f}_{\mathrm{o}}-\mathrm{f}_{\mathrm{e}}\right)^{2}}{\mathrm{f}_{\mathrm{e}}} \\
& =\frac{(12-14.4)^{2}}{14.4}+\frac{(108-105.6)^{2}}{105.6}+\frac{(24-21.6)^{2}}{21.6}+\frac{(156-158.4)^{2}}{158.4}=0.7576
\end{aligned}
$$

Step (4): Rule: If $\chi_{\text {stat }>3.841}^{2}$, Reject $\mathrm{H}_{0}$, otherwise, do not reject $\mathrm{H}_{0}$

0.7576

Step (5): Decision: Do not reject $\mathrm{H}_{0}$
So we do not reject $\mathrm{H}_{0}$ and conclude that there is insufficient evidence that the two proportions are different at $\alpha=0.05$

Critical Values of $\chi^{2}$
For a particular number of degrees of freedom, entry represents the critical value of $\chi^{2}$
corresponding to the cumulative probability ( $1-\alpha$ ) and a specified upper-tail area ( $\alpha$ ).

| Degrees of Freedom | Cumulative Probabilities |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0.005 | 0.01 | 0.025 | 0.05 | 0.10 | 0.25 | 0.75 | 0.90 | 0.95 | 0.975 | 0.99 | 0.995 |
|  | Upper-Tail Areas ( $\alpha$ ) |  |  |  |  |  |  |  |  |  |  |  |
|  | 0.995 | 0.99 | 0.975 | 0.95 | 0.90 | 0.75 | 0.25 | 0.10 | 0.05 | 0.025 | 0.01 | 0.005 |
| 1 |  |  | 0.001 | 0.004 | 0.016 | 0.102 | 1.323 | 2.706 | $3.841$ | 5.024 | 6.635 | 7.879 |
| 2 | 0.010 | 0.020 | 0.051 | 0.103 | 0.211 | 0.575 | 2.773 | 4.605 | 5.991 | 7.378 | 9.210 | 10.597 |
| 3 | 0.072 | 0.115 | 0.216 | 0.352 | 0.584 | 1.213 | 4.108 | 6.251 | 7.815 | 9.348 | 11.345 | 12.838 |
| 4 | 0.207 | 0.297 | 0.484 | 0.711 | 1.064 | 1.923 | 5.385 | 7.779 | 9.488 | 11.143 | 13.277 | 14.860 |
| 5 | 0.412 | 0.554 | 0.831 | 1.145 | 1.610 | 2.675 | 6.626 | 9.236 | 11.071 | 12.833 | 15.086 | 16.750 |
| 6 | 0.676 | 0.872 | 1.237 | 1.635 | 2.204 | 3.455 | 7.841 | 10.645 | 12.592 | 14.449 | 16.812 | 18.548 |

Example (2): (Textbook : P411-415 / Example11.1)
The following table is the contingency table for the hotel guest satisfaction study. The contingency table has two rows, indicating whether the guest would return to the hotel or would not return to the hotel, and two columns, one for each hotel. The cells in the table indicate the frequency of each row-and-column combination. The row totals indicate the number of quests who would return to the hotel and the number of guests who would not return to the hotel. The column totals are the sample sizes for each hotel location.

| Choose Hotel Again | Hotel |  |  |
| :---: | :---: | :---: | :---: |
|  | Beachcomber | Windsurfer | Total |
| Yes | 163 | 154 | 317 |
| No | 64 | 108 | 172 |
| Total | 227 | 262 | 489 |

Test where the Proportion of guests who would return Beachcomber, $\pi_{1}$, is equal to the population proportion of guests who would return to the Windsurfer, $\pi_{2}$,you can use the Chi-Square test for the difference between two proportion. $(\alpha=0.05)$

## Solution

## Step (1):

$\mathrm{H}_{0}: \pi_{1}=\pi_{2}$ (There is no difference between the two population Proportion)
$H_{1}: \pi_{1} \neq \pi_{2}$ (The population Proportion are not the same)
If $\mathrm{H}_{0}$ is true, there is no difference between the proportions of guests who are likely to choose either of these hotels again
Step (2): level of significance ( $\alpha=0.05$ )
$\chi_{(r-1)(c-1), \alpha}^{2}=\chi_{(2-1)(2-1), 0.05=}^{2} \chi_{1 \times 1,0.05=}^{2}=\chi_{1,0.05=3.841}^{2}$

Step (3): The test statistic

| Choose Hotel Again | Hotel |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Beachcomber |  | Windsurfer |  |
| Yes | $163 \quad 147.16$ | 154 | 169.84 | 317 |
| No | 64 | 79.84 | 108 | 92 |
| Total | 227 | 262 |  | 172 |

$f_{e}=\frac{\text { rowtotal } \times \text { columntotal }}{n}$
$f_{\text {row, } \text { column }}=f_{r, c}$
For example: $\mathrm{f}_{11}=\frac{317 \times 227}{489}=147.16, \mathrm{f}_{12}=\frac{317 \times 262}{489}=169.84$,

$$
\mathrm{f}_{21}=\frac{172 \times 227}{489}=79.84, \mathrm{f}_{22}=\frac{172 \times 262}{489}=92.16
$$

Totals for the observaed and expected frequencies are the same
Totals for the observaed frequencies $=163+154+64+108=489$
Totals for the expected frequencies $=147.16+169.84+79.84+92.16=489$

$$
\begin{aligned}
\chi_{S T A T}^{2} & =\sum_{\text {all cells }} \frac{\left(\mathrm{f}_{\mathrm{o}}-\mathrm{f}_{\mathrm{e}}\right)^{2}}{\mathrm{f}_{\mathrm{e}}} \\
& =\frac{(163-147.16)^{2}}{147.16}+\frac{(154-169.84)^{2}}{169.84}+\frac{(64-79.84)^{2}}{79.84}+\frac{(108-92.16)^{2}}{92.16}=9.048
\end{aligned}
$$

Step (4): Decision Rule: If $\chi_{\text {stat }>3.841}^{2}$ Reject $\mathrm{H}_{0}$

Step (5): Decision: Reject $\mathrm{H}_{0}$
Since the test statistic is greater than the critical value, there is sufficient evidence to conclude there is a significant difference between the proportions of guests who would return to Beachcomber is different from the proportion of guests who would return to the Windsurfer

Critical Values of $\chi^{2}$
For a particular number of degrees of freedom, entry represents the critical value of $\chi^{2}$ corresponding to the cumulative probability $(1-\alpha)$ and a specified upper-tail area $(\alpha)$.

| Degrees of Freedom | Cumulative Probabilities |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0.005 | 0.01 | 0.025 | 0.05 | 0.10 | 0.25 | 0.75 | 0.90 | 0.95 | 0.975 | 0.99 | 0.995 |
|  | Upper-Tail Areas (a) |  |  |  |  |  |  |  |  |  |  |  |
|  | 0.995 | 0.99 | 0.975 | 0.95 | 0.90 | 0.75 | 0.25 | 0.10 | 0.05 | 0.025 | 0.01 | 0.005 |
| 1 |  |  | 0.001 | 0.004 | 0.016 | 0.102 | 1.323 | 2.706 | $3.841$ | 5.024 | 6.635 | 7.879 |
| 2 | 0.010 | 0.020 | 0.051 | 0.103 | 0.211 | 0.575 | 2.773 | 4.605 | 5.991 | 7.378 | 9.210 | 10.597 |
| 3 | 0.072 | 0.115 | 0.216 | 0.352 | 0.584 | 1.213 | 4.108 | 6.251 | 7.815 | 9.348 | 11.345 | 12.838 |
| 4 | 0.207 | 0.297 | 0.484 | 0.711 | 1.064 | 1.923 | 5.385 | 7.779 | 9.488 | 11.143 | 13.277 | 14.860 |
| 5 | 0.412 | 0.554 | 0.831 | 1.145 | 1.610 | 2.675 | 6.626 | 9.236 | 11.071 | 12.833 | 15.086 | 16.750 |
| 6 | 0.676 | 0.872 | 1.237 | 1.635 | 2.204 | 3.455 | 7.841 | 10.645 | 12.592 | 14.449 | 16.812 | 18.548 |

## Chi-Square Test for the difference among more than two proportions.

Step (1): State the null and alternate hypotheses :
$\mathrm{H}_{0}$ : The proportions should be the same
$\mathrm{H}_{1}$ : The proportions should not be the same
Step (2): Select the level of significance ( $\alpha$ )
Step (3): The test statistic

$$
\chi_{S T A T}^{2}=\sum_{\text {all cells }} \frac{\left(f_{o}-f_{e}\right)^{2}}{f_{e}}
$$

- where:
$\mathrm{f}_{\mathrm{o}}=$ observed frequency in a particular cell of the $2^{*} \mathrm{c}$ table.
$\mathrm{f}_{\mathrm{e}}=$ expected frequency in a particular cell if $\mathrm{H}_{0}$ is true
(Assumed: each cell in the contingency table has expected frequency of at least 1 )
"Slide 15"
$f_{e}=\frac{\text { rowtotal } \times \text { columntotal }}{n}$
Or

$$
\overline{\mathrm{P}} * \text { Observed frequency in a particular cell } .
$$

$\overline{\mathrm{P}}$ : the overall Porportion $=\frac{X_{1}+X_{2}+\cdots \ldots+X_{c}}{n_{1}+n_{2}+\cdots \ldots .+n_{c}}=\frac{X}{n}$
"Slide 16"
Step (4): The critical value: $\mathrm{df}=(\mathrm{r}-1)(\mathrm{c}-1)=(2-1)(\mathrm{c}-1)=(\mathrm{c}-1)$
$\chi_{(\alpha,(c-1)}^{2}$
Step (5) : The $\chi_{\text {Stat }}^{2} \quad$ test statistic approximately follows a chi-squared distribution Reject $\mathrm{H}_{0}$ If $\quad \chi_{\text {Stat }}^{2}>\chi_{(\alpha,(c-1)}^{2}$ otherwise, do not reject $\mathrm{H}_{0}$

## Example (3):

Most companies consider big data analytics critical to success .However, is there a difference among small ( $<100$ employees), mid-size (100-999 employees), and large ( $1000+$ employees) companies in the proportion of companies that have already deployed big data project? A study showed the results for the different company size.
(Data extracted from 2014 big data outlook:big data is transformative -where is your company? )

| Have already <br> deployed big <br> data projects | Company Size |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Small | Mid-sized | large | Total |
| Ye | 18 | 74 | 52 | 144 |
| No | 182 | 126 | 148 | 456 |
| Total | 200 | 200 | 200 | 600 |

Assume that 200 decision makers involved in big data purchases within each company size were surveyed. At the 0.05 level of significance, is there evidence of a difference among companies of different sizes with respect to the proportion of companies that have already deployed big data projects?

## Solution

## Step (1):

$\mathrm{H}_{0}: \pi_{1}=\pi_{2}=\pi_{3}$
$\mathrm{H}_{1}$ : At least one proportion differs where $\pi_{1}=$ small, $\pi_{2}=$ medium, $\pi_{3}=$ large
If $\mathrm{H}_{0}$ is true, there is no difference between the three proportions.
Step (2): The level of significance ( $\alpha=0.05$ )
$\chi_{(r-1)(c-1), \alpha}^{2}=\chi_{(2-1)(3-1), 0.05=}^{2} \chi_{1 \times 2,0.05=}^{2}=\chi_{2,0.05=5.991}^{2}$

## Step (3):

| Have already deployed big data projects | Company Size |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | Small | Mid-sized | large | Total |
| Ye | 18 - 48 | 74 48 | 52 48 | 144 |
| No | $182-152$ | 126152 | 148 152 | 456 |
| Total | 200 | 200 | 200 | 600 |

where:
$\mathrm{f}_{\mathrm{o}}=$ observed frequency in a particular cell
$\mathrm{f}_{\mathrm{e}}=$ expected frequency in a particular cell if $\mathrm{H}_{0}$ is true
$f_{e}=\frac{\text { rowtotal } \times \text { columntotal }}{n}$
$f_{\text {row, } \text { column }}=f_{r, c}$
For example: $\mathrm{f}_{11}=\frac{144 \times 200}{600}=48, \mathrm{f}_{12}=\frac{144 \times 200}{600}=48, \mathrm{f}_{13}=\frac{144 \times 200}{600}=48$,

$$
\mathrm{f}_{21}=\frac{456 \times 200}{600}=152, \mathrm{f}_{22}=\frac{456 \times 200}{600}=152, \mathrm{f}_{23}=\frac{456 \times 200}{600}=152
$$

Totals for the observaed and expected frequencies are the same
Totals for the observaed frequencies $=18+74+52+182+126+148=600$
Totals for the expected frequencies $=48+48+48+152+152+152=600$

$$
\begin{aligned}
\chi_{S T A T}^{2} & =\sum_{\text {all cells }} \frac{\left(\mathrm{f}_{\mathrm{o}}-\mathrm{f}_{\mathrm{e}}\right)^{2}}{\mathrm{f}_{\mathrm{e}}} \\
& =\frac{(18-48)^{2}}{48}+\frac{(74-48)^{2}}{48}+\frac{(52-48)^{2}}{48}+\frac{(182-152)^{2}}{152}+\frac{(126-152)^{2}}{152}+\frac{(148-152)^{2}}{152}=43.64035
\end{aligned}
$$

Step (4): Decision Rule: If $\chi_{\text {stat>5.991 }}^{2}$ Reject $H_{0}$, otherwise, do not reject H0 Step (5):
Since $\chi_{\text {stat }}^{2}=43.64035$ is greater than the upper critical value of 5.991, reject H0 .There is evidence among the groups with respect to the proportion of companies that have already deployed big data projects

## Chi-Square Test of independent.

Similar to the $\chi^{2}$ test for equality of more than two proportions, but extends the concept to contingency tables with r rows and c columns (Slide 17)
The test is applied when you have two categorical variables from a single population, and it is used to determine whether there is a significant association between the two variables.
Step (1): State the null and alternate hypotheses :
$\mathrm{H}_{0}$ : The two categorical variables are independent
(i.e., there is no relationship between them)
$\mathrm{H}_{1}$ : The two categorical variables are dependent
(i.e., there is a relationship between them)

Step (2): Select the level of significance ( $\alpha$ )
Step (3): The test statistic

$$
\chi_{S T A T}^{2}=\sum_{\text {all cells }} \frac{\left(f_{o}-f_{e}\right)^{2}}{f_{e}}
$$

■ where:
$\mathrm{f}_{\mathrm{o}}=$ observed frequency in a particular cell of th $\mathrm{r} * \mathrm{c}$ table
$\mathrm{f}_{\mathrm{e}}=$ expected frequency in a particular cell if $\mathrm{H}_{0}$ is true
(Assumed: each cell in the contingency table has expected frequency of at least 1 )
"Slide 18"
$f_{e}=\frac{\text { rowtotal } \times \text { columntotal }}{n}$

Step (4): The critical value:
$\mathrm{df}=(\mathrm{r}-1)(\mathrm{c}-1) \chi_{(\alpha,(r-1)(c-1))}^{2}$
Step (5) : The $\chi_{\text {Stat }}^{2} \quad$ test statistic approximately follows a chi-squared distribution Reject $\mathrm{H}_{\mathrm{o}}$ If $\quad \chi_{\text {stat }}^{2}>\chi_{(\alpha,((r-1)(c-1))}^{2}$

Example (4): Slide(21-25)
The meal plan selected by 200 students is shown below:

| Class | Number of meals per week |  |  | Total |
| :---: | :---: | :---: | :---: | :---: |
|  | 20/week | $\mathbf{1 0} /$ week | none |  |
| Fresh. | 24 | 32 | 14 | 70 |
| Soph. | 22 | 26 | 12 | 60 |
| Junior | 10 | 14 | 6 | 30 |
| Senior | 14 | 16 | 10 | 40 |
| Total | 70 | 88 | 42 | 200 |

At the 0.05 level of significance, is there evidence that meal plan and class standing are independent(i.e., there is no relationship between them)

## Solution

## Step (1):

$\mathrm{H}_{0}$ : Meal plan and class standing are independent
(i.e., there is no relationship between them)
$\mathrm{H}_{1}$ : Meal plan and class standing are dependent
(i.e., there is a relationship between them)

Step (2): The level of significance ( $\alpha=0.05$ )
$\chi_{(r-1)(c-1), \alpha}^{2}=\chi_{(4-1)(3-1), 0.05=}^{2} \chi_{3 \times 2,0.05}^{2}=\chi_{6,0.05=12.592}^{2}$
Degree of freedom=(4-1)(3-1)=6

## Step (3):

| Class <br> Standing | Number of meals per week |  |  | Total |
| :---: | :---: | :---: | :---: | :---: |
|  | 20/week | 10/week | none |  |
| Fresh. | 24.24 .5 | 3230.8 | 14 14.7 | 70 |
| Soph. | 22.21 | 26 26.4 | 1212.6 | 60 |
| Junior | 10 10.5 | $14 \quad 13.2$ | $6 \quad 6.3$ | 30 |
| Senior | 14.14 | 16.17 .6 | 10 8.4 | 40 |
| Total | 70 | 88 | 42 | 200 |

where:
$f_{o}=$ observed frequency in a particular cell
$\mathrm{f}_{\mathrm{e}}=$ expected frequency in a particular cell if $\mathrm{H}_{0}$ is true
$f_{e}=\frac{\text { rowtotal } \times \text { columntotal }}{n}$
$f_{\text {row }, \text { column }}=f_{r, c}$
For example: $f_{11}=\frac{70 \times 70}{200}=24.5, f_{12}=\frac{70 \times 88}{200}=30.8, f_{13}=\frac{70 \times 42}{200}=14.7$,

$$
\begin{aligned}
& \mathrm{f}_{21}=\frac{60 \times 70}{200}=21, \mathrm{f}_{22}=\frac{60 \times 88}{200}=26.4, \mathrm{f}_{23}=\frac{60 \times 42}{200}=12.6, \\
& \mathrm{f}_{31}=\frac{30 \times 70}{200}=10.5, \mathrm{f}_{32}=\frac{30 \times 88}{200}=13.2, \mathrm{f}_{33}=\frac{30 \times 42}{200}=6.3, \\
& \mathrm{f}_{41}=\frac{40 \times 70}{200}=14, \mathrm{f}_{42}=\frac{40 \times 88}{200}=17.6, \mathrm{f}_{43}=\frac{40 \times 42}{200}=8.4,
\end{aligned}
$$

Totals for the observaed and expected frequencies are the same
Totals for the observaed frequencies $=24+32+14+22+26+12+10+14+6+14+16+10=200$
Totals for the expected frequencies
$=24.5+30.8+14.7+21+26.4+12.6+10.5+13.2+6.3+14+17.6+8.4=200$

$$
\begin{aligned}
\chi_{\text {STAT }}^{2}= & \sum_{\text {all cells }} \frac{\left(\mathrm{f}_{\mathrm{o}}-\mathrm{f}_{\mathrm{e}}\right)^{2}}{\mathrm{f}_{\mathrm{e}}} \\
= & \frac{(24-24,5)^{2}}{24.5}+\frac{(32-30.8)^{2}}{30.8}+\frac{(14-14.8)^{2}}{14.8}+\frac{(22-21)^{2}}{21}+\frac{(26-26.4)^{2}}{26.4}+\frac{(12-12.6)^{2}}{12.6} \\
& +\frac{(10-10.5)^{2}}{10.5}+\frac{(14-13.2)^{2}}{13.2}+\frac{(6-6.3)^{2}}{6.3}+\frac{(14-14)^{2}}{14}+\frac{(16-17.6)^{2}}{17.6}+\frac{(10-8.4)^{2}}{8.4}=0.709
\end{aligned}
$$

Step (4): Decision Rule: If $\chi_{\text {stat }>12.592}^{2}$ Reject $\mathrm{H}_{0}$, otherwise, do not reject H0

Step (5): Here, $\chi_{\text {stat }=0.709<\chi_{0.05}^{2}=12.592 \text {, }, ~=10 .}^{2}$
so do not reject $\mathrm{H}_{0}$
Conclusion: there is insufficient evidence that meal plan and class standing are related at
$\alpha=0.05$

| Critical Values of $\chi^{2}$ <br> For a particular number of degrees of freedom, entry represents the critical value of $\chi^{2}$ corresponding to the cumulative probability $(1-\alpha)$ and a specified upper-tail area ( $\alpha$ ). |  |  |  |  |  |  |  |  |  |  |  |  |
