## Course Contents

Chapter 1: Physics and Measurement
Chapter 2: Motion in One Dimension
Chapter 3: Vectors
Chapter 4: Motion in Two Dimensions
Chapter 5: Laws of Motion
Chapter 6: Circular Motion: Applications of Newton's Laws
Chapter 7: Energy and Energy Transfer
Chapter 8: Potential Energy
Chapter 9: Static Equilibrium and Elasticity
Chapter 10: Fluid Mechanics

## Chapter 4:

## Motion in Two Dimensions

## Position, average velocity and instantaneous velocity

$>$ Position vector is defined by vector $r$.
$>$ The displacement vector is $\Delta \mathrm{r}$.

$$
\overrightarrow{\mathbf{v}}_{\mathrm{avg}} \equiv \frac{\Delta \overrightarrow{\mathbf{r}}}{\Delta t}
$$

$>$ The average velocity is defined as:

$$
\overrightarrow{\mathbf{v}} \equiv \lim _{\Delta t \rightarrow 0} \frac{\Delta \overrightarrow{\mathbf{r}}}{\Delta t}=\frac{d \overrightarrow{\mathbf{r}}}{d t}
$$

$>$ The average acceleration is

$$
\overrightarrow{\mathbf{a}}_{\mathrm{avg}} \equiv \frac{\Delta \overrightarrow{\mathbf{v}}}{\Delta t}=\frac{\overrightarrow{\mathbf{v}}_{f}-\overrightarrow{\mathbf{v}}_{i}}{t_{f}-t_{i}}
$$

## Acceleration

$>$ The average acceleration is

$$
\overline{\mathbf{a}} \equiv \frac{\mathbf{v}_{f}-\mathbf{v}_{i}}{t_{f}-t_{i}}=\frac{\Delta \mathbf{v}}{\Delta t}
$$

Instantaneous acceleration

$$
\mathbf{a} \equiv \lim _{\Delta t \rightarrow 0} \frac{\Delta \mathbf{v}}{\Delta t}=\frac{d \mathbf{v}}{d t}
$$

$>$ Caution: In vector change calculations, magnitude may change, or direction, or both.

## Two dimensional motion with constant acceleration

- Position

$$
\mathbf{r}=x \hat{\mathbf{i}}+y \hat{\mathbf{j}}
$$

- Velocity

$$
\begin{aligned}
\mathbf{v} & =\frac{d \mathbf{r}}{d t}=\frac{d x}{d t} \hat{\mathbf{i}}+\frac{d y}{d t} \hat{\mathbf{j}}=v_{x} \hat{\mathbf{i}}+v_{y} \hat{\mathbf{j}} \\
\mathbf{v}_{f} & =\left(v_{x i}+a_{x} t\right) \hat{\mathbf{i}}+\left(v_{y i}+a_{y} t \hat{\mathbf{j}}\right. \\
& =\left(v_{x i} \hat{\mathbf{i}}+v_{y i} \hat{\mathbf{j}}\right)+\left(a_{x} \hat{\mathbf{i}}+a_{y} \hat{\mathbf{j}}\right) t \\
\mathbf{v}_{f} & =\mathbf{v}_{i}+\mathbf{a} t \\
x_{f} & =x_{i}+v_{x i} t+\frac{1}{2} a_{x} t^{2} \quad y_{f}=y_{i}+v_{y i} t+\frac{1}{2} a_{y} t^{2} \\
\mathbf{r}_{f} & =\left(x_{i}+v_{x i} t+\frac{1}{2} a_{x} t^{2}\right) \hat{\mathbf{i}}+\left(y_{i}+v_{y i} t+\frac{1}{2} a_{y} t^{2}\right) \hat{\mathbf{j}} \\
& =\left(x_{i} \hat{\mathbf{i}}+y_{i} \hat{\mathbf{j}}\right)+\left(v_{x i} \hat{\mathbf{i}}+v_{y i} \hat{\mathbf{j}}\right) t+\frac{1}{2}\left(a_{x} \hat{\mathbf{i}}+a_{y} \hat{\mathbf{j}}\right) t^{2} \\
\mathbf{r}_{f} & =\mathbf{r}_{i}+\mathbf{v}_{i} t+\frac{1}{2} \mathbf{a} t^{2}
\end{aligned}
$$

## Example:

A particle starts from the origin at $t=0$ with an initial velocity having an $x$ component of $20 \mathrm{~m} / \mathrm{s}$ and a $y$ component of $-15 \mathrm{~m} / \mathrm{s}$. The particle moves in the $x y$ plane with an $x$ component of acceleration only, given by $a_{x}=4.0 \mathrm{~m} / \mathrm{s}^{2}$.
(A) Determine the components of the velocity vector at any time and the total velocity vector at any time.
(B) Calculate the velocity and speed of the particle at $t=5.0 \mathrm{~s}$.
(C) Determine the $x$ and $y$ coordinates of the particle at any time $t$ and the position vector at this time.
A)

## Solution:

a. $\quad v_{x f}=v_{x i}+a_{x} t=(20+4.0 t) \mathrm{m} / \mathrm{s}$
$v_{y f}=v_{y i}+a_{y} t=-15 \mathrm{~m} / \mathrm{s}+0=-15 \mathrm{~m} / \mathrm{s}$
$\mathbf{v}_{f}=v_{x i} \hat{\mathbf{i}}+v_{y i} \hat{\mathbf{j}}=[(20+4.0 t) \hat{\mathbf{i}}-15 \hat{\mathbf{j}}] \mathrm{m} / \mathrm{s}$
b. $\quad \mathbf{v}_{f}=[(20+4.0(5.0)) \hat{\mathbf{i}}-15 \hat{\mathbf{j}}] \mathrm{m} / \mathrm{s}=(40 \hat{\mathbf{i}}-15 \hat{\mathbf{j}}) \mathrm{m} / \mathrm{s}$

$$
\begin{aligned}
v_{f}=\left|\mathbf{v}_{f}\right|=\sqrt{v_{x f}^{2}+v_{y f}^{2}} & =\sqrt{(40)^{2}+(-15)^{2}} \mathrm{~m} / \mathrm{s} \\
& =43 \mathrm{~m} / \mathrm{s}
\end{aligned}
$$

$$
\theta=\tan ^{-1}\left(\frac{v_{y f}}{v_{x f}}\right) \quad \Theta=360-21=339^{\circ}
$$

c.

$$
\begin{gathered}
x_{f}=v_{x i} t+\frac{1}{2} a_{x} t^{2}=\left(20 t+2.0 t^{2}\right) \mathrm{m} \\
y_{f}=v_{y i} t=(-15 t) \mathrm{m} \\
\mathbf{r}_{f}=x_{f} \hat{\mathbf{i}}+y_{f} \hat{\mathbf{j}}=\left[\left(20 t+2.0 t^{2}\right) \hat{\mathbf{i}}-15 t \hat{\mathbf{j}}\right] \mathrm{m} \\
r_{f}=\left|\mathbf{r}_{f}\right|=\sqrt{(150)^{2}+(-75)^{2}} \mathrm{~m}=170 \mathrm{~m}
\end{gathered}
$$

## Projectile Motion

- Important to separate the two components in the calculations.
- Assumptions:
- $g$ is constant
- Air resistance is neglected

$$
\begin{aligned}
& \cos \theta_{i}=v_{x i} / v_{i} \quad \sin \theta_{i}=v_{y i} / v_{i} \\
& v_{x i}=v_{i} \cos \theta_{i} \quad v_{y i}=v_{i} \sin \theta_{i} \\
& x_{f}=v_{x i} t=\left(v_{i} \cos \theta_{i}\right) t \\
& t=x_{y} /\left(v_{i} \cos \theta_{i}\right)
\end{aligned}
$$

$$
y_{f}=v_{y i} t+\frac{1}{2} a_{y} t^{2}=\left(v_{i} \sin \theta_{i}\right) t-\frac{1}{2} g t^{2}
$$

$$
y=\left(\tan \theta_{i}\right) x-\left(\frac{g}{2 v_{i}^{2} \cos ^{2} \theta_{i}}\right) x^{2}
$$

Active Figure 4.7 The parabolic path of a projectile that leaves the origin with a velocity $\mathbf{v}_{i}$. The velocity vector $\mathbf{v}$ changes with time in both magnitude and direction. This change is the result of acceleration in the negative $y$ direction. The $x$ component of velocity remains constant in time because there is no acceleration along the horizontal direction. The $y$ component of velocity is zero at the peak of the path.

Figure 4.8 The position vector $\mathbf{r}_{f}$ of a projectile launched from the origin whose initial velocity at the origin is $\mathbf{v}_{i}$. The vector $\mathbf{v}_{i} t$ would be the displacement of the projectile if gravity were absent, and the vector $\frac{1}{2} \mathrm{~g} t^{2}$ is its vertical displacement due to its downward gravitational acceleration.

## Horizontal Range and Maximum Height of a Projectile

- Let us assume that a projectile is launched from the origin at $t_{i}=0$ with a positive $\boldsymbol{v}_{\boldsymbol{y}}$ component, as shown in Figure 4.10
Two points are especially interesting to analyze:
the peak point A , which has Cartesian coordinates ( $R / 2, h$ ), and the point $B$ which has coordinates $(\boldsymbol{R}, 0)$. The distance $\boldsymbol{R}$ is called the horizontal range of the projectile, and the distance $h$ is its maximum height. Let us find $h$ and $\boldsymbol{R}$ in terms of $\nu i, \theta i$, and $g$. We can determine $h$ by noting that at the peak, $v_{y A},=0$ Therefore, we can use
Equation 4.8a to determine the time $t_{\mathrm{A}}$ at which the projectile reaches the peak:

$$
\begin{aligned}
v_{y f} & =v_{y i}+a_{y} t \\
0 & =v_{i} \sin \theta_{i}-g t_{\mathrm{A}} \\
t_{\mathrm{A}} & =\frac{v_{i} \sin \theta_{i}}{g}
\end{aligned}
$$

Engineering Program

Figure 4.10 A projectile launched from the origin at $t_{i}=0$ with an initial velocity $\mathbf{v}_{i}$. The maximum height of the projectile is $h$, and the horizontal range is $R$. At (A), the peak of the trajectory, the particle has coordinates $(R / 2, h)$.

$$
\begin{aligned}
v_{y f} & =v_{y i}+a_{y} t \\
0 & =v_{i} \sin \theta_{i}-g t_{\mathrm{A}} \\
t_{\mathrm{A}} & =\frac{v_{i} \sin \theta_{i}}{g}
\end{aligned}
$$

Substituting this expression for $t_{\mathrm{A}}$ into the $y$ part of Equation 4.9a and replacing $y=y_{\mathrm{A}}$ with $h$, we obtain an expression for $h$ in terms of the magnitude and direction of the initial velocity vector:

$$
\begin{align*}
h & =\left(v_{i} \sin \theta_{i}\right) \frac{v_{i} \sin \theta_{i}}{g}-\frac{1}{2} g\left(\frac{v_{i} \sin \theta_{i}}{g}\right)^{2} \\
h & =\frac{v_{i}^{2} \sin ^{2} \theta_{i}}{2 g} \tag{4.13}
\end{align*}
$$

The range $R$ is the horizontal position of the projectile at a time that is twice the time at which it reaches its peak, that is, at time $t_{\mathrm{B}}=2 t_{\mathrm{A}}$. Using the $x$ part of Equation 4.9a, noting that $v_{x i}=v_{x \mathrm{~B}}=v_{i} \cos \theta_{i}$ and setting $x_{\mathrm{B}}=R$ at $t=2 t_{\mathrm{A}}$, we find that

$$
\begin{aligned}
R & =v_{x i} t_{\mathrm{B}}=\left(v_{i} \cos \theta_{i}\right) 2 t_{\mathrm{A}} \\
& =\left(v_{i} \cos \theta_{i}\right) \frac{2 v_{i} \sin \theta_{i}}{g}=\frac{2 v_{i}^{2} \sin \theta_{i} \cos \theta_{i}}{g}
\end{aligned}
$$

Using the identity $\sin 2 \theta=2 \sin \theta \cos \theta$ (see Appendix B.4), we write $R$ in the more compact form

$$
\begin{equation*}
R=\frac{v_{i}^{2} \sin 2 \theta_{i}}{g} \tag{4.14}
\end{equation*}
$$

The maximum value of $R$ from Equation 4.14 is $R_{\max }=v_{i}^{2} / \mathrm{g}$. This result follows from the fact that the maximum value of $\sin 2 \theta_{i}$ is 1 , which occurs when $2 \theta_{i}=90^{\circ}$. Therefore, $R$ is a maximum when $\theta_{i}=45^{\circ}$.

Example: A long-jumper (Fig. 4.12) leaves the ground at an angle of $20.0^{\circ}$ above the horizontal and at a speed of $11.0 \mathrm{~m} / \mathrm{s}$.
(A) How far does he jump in the horizontal direction? (Assume his motion is equivalent to that of a particle.)
(B) What is the maximum height reached?

Solution, A
$x_{f}=x_{\mathrm{B}}=\left(v_{i} \cos \theta_{i}\right) t_{\mathrm{B}}=(11.0 \mathrm{~m} / \mathrm{s})\left(\cos 20.0^{\circ}\right) t_{\mathrm{B}}$
$v_{y f}=v_{y \mathrm{~A}}=v_{i} \sin \theta_{i}-g t_{\mathrm{A}}$
$0=(11.0 \mathrm{~m} / \mathrm{s}) \sin 20.0^{\circ}-\left(9.80 \mathrm{~m} / \mathrm{s}^{2}\right) t_{\mathrm{A}}$
$t_{\mathrm{A}}=0.384 \mathrm{~s}$

$$
R=\frac{v_{i}^{2} \sin 2 \theta_{i}}{g}
$$

$$
t_{\mathrm{B}}=2 t_{\mathrm{A}}=0.768 \mathrm{~s} .
$$

$$
x_{f}=x_{\mathrm{B}}=(11.0 \mathrm{~m} / \mathrm{s})\left(\cos 20.0^{\circ}\right)(0.768 \mathrm{~s})=7.94 \mathrm{~m}
$$

Solution, B

$$
\begin{aligned}
y_{\text {max }} & =y_{\mathrm{A}}=\left(v_{i} \sin \theta_{i}\right) t_{\mathrm{A}}-\frac{1}{2} g t_{\mathrm{A}}{ }^{2} \\
& =(11.0 \mathrm{~m} / \mathrm{s})\left(\sin 20.0^{\circ}\right)(0.384 \mathrm{~s})
\end{aligned}
$$

$$
h=\frac{v_{i}^{2} \sin ^{2} \theta_{i}}{2 g}
$$

$$
-\frac{1}{2}\left(9.80 \mathrm{~m} / \mathrm{s}^{2}\right)(0.384 \mathrm{~s})^{2}=0.722 \mathrm{~m}
$$

## Uniform Circular Motion

- Figure ... shows a car moving in a circular path with constant speed $v$. Such motion is called uniform circular motion, and occurs in many situations. It is often surprising to students to find that even though an object moves at a constant speed in a circular path, it still has an acceleration.
- The velocity vector is always tangent to the path of the object and perpendicular to the radius of the circular path. We now show that the acceleration vector in uniform circular motion is always perpendicular to the path and always points toward the center of the circle. An acceleration of this nature is called a centripetal acceleration (centripetal means center-seeking).

## Uniform Circular Motion

- The magnitude of centripetal acceleration:

$$
a_{c}=\frac{v^{2}}{r}
$$

$\mathrm{a}_{\mathrm{c}}$ : centripetal acceleration
v : is the velocity
$r$ : is the radius of circular path

The time required for one complete revolution.
 T : is the period,

$$
T \equiv \frac{2 \pi r}{v}
$$

Example: a car moves at a constant speed of $10 \mathrm{~m} / \mathrm{s}$ around a circular path with radius $\mathbf{2 5} \mathbf{~ m}$. Find the following:

## A: The centripetal acceleration

## B: The period

$$
\begin{gathered}
a_{c}=\frac{v^{2}}{r} \\
T \equiv \frac{2 \pi r}{v}
\end{gathered}
$$

Solution:
A:

$$
\mathrm{a}_{\mathrm{c}}=\mathrm{v}^{2} / \mathrm{r}=10^{2} / 25=4 \mathrm{~m} / \mathrm{s}^{2}
$$

B: $\quad \mathrm{T}=2 * \pi * 25 / 10=15.71 \mathrm{~s}$

## Tangential and Radial Acceleration

- Total acceleration

$$
\mathbf{a}=\mathbf{a}_{r}+\mathbf{a}_{t}
$$

- Tangential acceleration

$$
a_{t}=\frac{d|\mathbf{v}|}{d t}
$$

- Radial acceleration

$$
a_{r}=-a_{c}=-\frac{v^{2}}{r}
$$

Because $\mathbf{a}_{r}$ and $\mathbf{a}_{t}$ are perpendicular component vectors of $\mathbf{a}$, it follows that the magnitude of $\mathbf{a}$ is $a=\sqrt{a_{r}{ }^{2}+a_{t}{ }^{2}}$. At a given speed, $a_{r}$ is large when the radius of curvature is small (as at points (A) and © in Fig. 4.18) and small when $r$ is large (such as at point (C). The direction of $\mathbf{a}_{t}$ is either in the same direction as $\mathbf{v}$ (if $v$ is increasing) or opposite $\mathbf{v}$ (if $v$ is decreasing).

## Example:

A car exhibits a constant acceleration of $0.300 \mathrm{~m} / \mathrm{s}^{2}$ parallel to the roadway. The car passes over a rise in the roadway such that the top of the rise is shaped like a circle of radius 500 m . At the moment the car is at the top of the rise, its velocity vector is horizontal and has a magnitude of $6.00 \mathrm{~m} / \mathrm{s}$. What is the direction of the total acceleration vector for the car at this instant?

(a)

(b)

Solution:

$$
\begin{aligned}
a_{r} & =-\frac{v^{2}}{r}=-\frac{(6.00 \mathrm{~m} / \mathrm{s})^{2}}{500 \mathrm{~m}}=-0.0720 \mathrm{~m} / \mathrm{s}^{2} \\
a & =\sqrt{a_{r}^{2}+a_{t}^{2}}=\sqrt{(-0.0720)^{2}+(0.300)^{2}} \mathrm{~m} / \mathrm{s}^{2} \\
& =0.309 \mathrm{~m} / \mathrm{s}^{2}
\end{aligned}
$$

If $\phi$ is the angle between $\mathbf{a}$ and the horizontal, then

$$
\phi=\tan ^{-1} \frac{a_{r}}{a_{t}}=\tan ^{-1}\left(\frac{-0.0720 \mathrm{~m} / \mathrm{s}^{2}}{0.300 \mathrm{~m} / \mathrm{s}^{2}}\right)=-13.5^{\circ}
$$
